AI4M_C3_M3_lecture_notebook_gradcam_2

August 10, 2020

1 GradCAM: Continuation (Part 2) - Lecture Notebook

In the previous lecture notebook (GradCAM Part 1) we explored what Grad-Cam is and why it is useful. We also looked at how we can compute the activations of a particular layer using Keras API. In this notebook we will check the other element that Grad-CAM requires, the gradients of the model's output with respect to our desired layer's output. This is the "Grad" portion of Grad-CAM.

Let's dive into it!

Using TensorFlow backend.

The load_C3M3_model() function has been taken care of and as last time, its internals are out of the scope of this notebook.

Kindly recall from the previous notebook (GradCAM Part 1) that our model has 428 layers. We are now interested in getting the gradients when the model outputs a specific class. For this we will use Keras backend's gradients(...) function. This function requires two arguments:

- Loss (scalar tensor)
- List of variables

Since we want the gradients with respect to the output, we can use our model's output tensor:

However this is not a scalar (aka rank-0) tensor because it has axes. To transform this tensor into a scalar we can slice it like this:

```
In [7]: y = y[0]
```

Out[7]: <tf.Tensor 'strided_slice_2:0' shape=(14,) dtype=float32>

It is still *not* a scalar tensor so we will have to slice it again:

```
In [8]: y = y[0]
```

Out[8]: <tf.Tensor 'strided_slice_3:0' shape=() dtype=float32>

Now it is a scalar tensor!

The above slicing could be done in a single statement like this:

```
y = y[0,0]
```

But the explicit version of it was shown for visibility purposes.

The first argument required by gradients(..) function is the loss, which we will like to get the gradient of, and the second is a list of parameters to compute the gradient with respect to. Since we are interested in getting the gradient of the output of the model with respect to the output of the last convolutional layer we need to specify the layer as we did in the previous notebook:

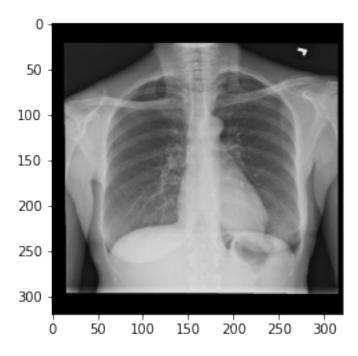

Notice that the gradients function returns a list of placeholder tensors. To get the actual placeholder we will get the first element of this list:

```
Out[12]: <tf.Tensor 'gradients_1/AddN:0' shape=(?, ?, ?, 1024) dtype=float32>
```

As with the activations of the last convolutional layer in the previous notebook, we still need a function that uses this placeholder to compute the actual values for an input image. This can be done in the same manner as before. Remember this **function expects its arguments as lists or tuples**:

Out[13]: <keras.backend.tensorflow_backend.Function at 0x7fa2940b1320>

Now that we have the function for computing the gradients, let's test it out on a particular image. Don't worry about the code to load the image, this has been taken care of for you, you should only care that an image ready to be processed will be saved in the x variable:

We should normalize this image before going forward, this has also been taken care of:

Now we have everything we need to compute the actual values of the gradients. In this case we should also **provide the input as a list or tuple**:

An important intermediary step is to trim the batch dimension which can be done like this:

```
In [17]: # Remove batch dimension
        actual_gradients = actual_gradients[0][0, :]
In [18]: # Print shape of the gradients array
        print(f"Gradients of model's output with respect to output of last convolutional layer
        # Print gradients array
        actual_gradients
Gradients of model's output with respect to output of last convolutional layer have shape: (10
Out[18]: array([[[-1.4380310e-09, 2.8972802e-09, 3.3952352e-07, ...,

```

Looks like everything worked out nicely! You will still have to wait for the assignment to see how these elements are used by Grad-CAM to get visual interpretations. Before you go you should know that there is a shortcut for these calculations by getting both elements from a single Keras function:

```
In [19]: # Save multi-input Keras function in a variable
         activations_and_gradients_function = K.function([model.input], [layer.output, gradien
          # Run the function on our image
         act_x, grad_x = activations_and_gradients_function([x])
         # Remove batch dimension for both arrays
         act x = act x[0, :]
         grad x = grad x[0, :]
In [20]: # Print actual activations
         print(act_x)
         # Print actual gradients
         print(grad_x)

Congratulations on finishing this lecture notebook! Hopefully you will now have a better understanding of how to leverage Keras's API power for computing gradients. Keep it up!
